CASE EXPLANATION:

29-year-old male was referred to the Emergency Department (ED) for suspected traumatic brain injury. He was involved in a motor vehicle accident (MVA) two days prior and sustained a close fracture of the right tibia and left radius. He started to have headache and vomiting a day after his MVA.

Patient was febrile, tachycardic, tachypneic and hypotensive. Petechial rash was visible around his neck and chest (Fig 1,2), and he had bilateral basal lung crepitations. High flow oxygen was administered with fluid resuscitation. Patient had type I respiratory failure on arterial blood gas review. Bedside Focused Echocardiography and repeated FAST scans were unremarkable. Chest radiograph showed diffuse bilateral pulmonary infiltrates (Fig 4). CT brain showed no intracranial haemorrhage or focal brain lesion.

A diagnosis of Fat Embolism Syndrome (FES) was made. Patient was admitted to the Intensive Care Unit for supportive treatment and his right lower limb fracture was surgically fixed the next day. Patient made an uneventful recovery and was discharged a week later.
